

- 1) If the user interrupts *during* the manipulation of the data structure, the signal handler will attempt to lock the data, but the data has never been unlocked from **some_function**. So, it will run into a deadlock/infinite wait since the signal handler will keep trying to control the data access, but it won't ever be able to. The issue is that we shouldn't use regular spin locks in signal handlers. Corrected code available in file **patched_handler.c**
